

# **Structure of Water and Hydrogen Bonding**

# Chemistry Review

## Matter

Anything that takes up **space** and has **mass**

- Rocks, metals, oils, gases, organisms, etc. are all forms of matter

## Element

A substance that cannot be broken down into other substances by chemical reactions

- **92** elements occur in nature
- Periodic table

## Compound

A substance consisting of **two or more** different **elements** combined in a fixed ratio

- $\text{H}_2\text{O}$
- $\text{NaCl}$

Essential elements: of the 92 naturally occurring elements 20-25% are essential to survive and reproduce. **CHOPN** make up 96% of living matter

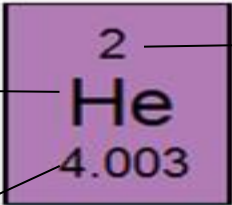

Trace elements: of the 92 naturally occurring elements, these are required by an organism in very small quantities

# Essential Elements

- Search up the essential elements. Why are they essential? (i.e. what major roles do these elements play in the human body?)
- Search up trace elements. What are a few examples of trace elements and their purpose in the human body?

# Chemistry Review

Element symbol ←  Atomic number:  
number of protons

Atomic mass: number of protons  
plus neutrons averaged over all  
isotopes

Atomic mass: number of protons plus neutrons averaged over all isotopes

# Bohr Model

- **Bohr Model**: shows electrons orbiting the nucleus of an atom
  - Electrons are placed on **shells** around the nucleus
  - Each shell is a different **energy level** and can hold up to a certain number of electrons
    - 1st shell: 2 e<sup>-</sup>
    - 2nd shell: 8 e<sup>-</sup>
    - 3rd shell: 18e<sup>-</sup>

# Bohr Models

Example: Lithium

# Lewis Dot Model

- **Lewis dot model**: simplified Bohr diagrams
  - Does not show energy levels
  - Only shows electrons in the **valence shell** (outermost shell)
  - Electrons are placed around the element symbol

# Lewis Dot Model

Example: Lithium

# Types of Bonds

- Elements want to be **stable**
  - Achieve this by forming chemical bonds with other elements
  - Octet rule: elements will gain, lose, or share electrons to complete their valence shell and become stable (like noble gases)

# Types of Bonds

**Chemical Bonds:** an attraction between two atoms, resulting from the sharing or transferring of valence electrons

**Electronegativity:** the measure of an atom's ability to attract electrons to itself

# Types of Bonds

- Covalent bonds: when two or more atoms **share** electrons (usually between two nonmetals)
  - Forms molecules and compounds
    - Single bond: 1 pair of shared e-
    - Double bond: 2 pairs of shared e-
    - Triple bond: 3 pairs of shared e-
  - There are **two** types of covalent bonds:  
**nonpolar covalent** and **polar covalent**

# Types of Bonds

- Nonpolar covalent

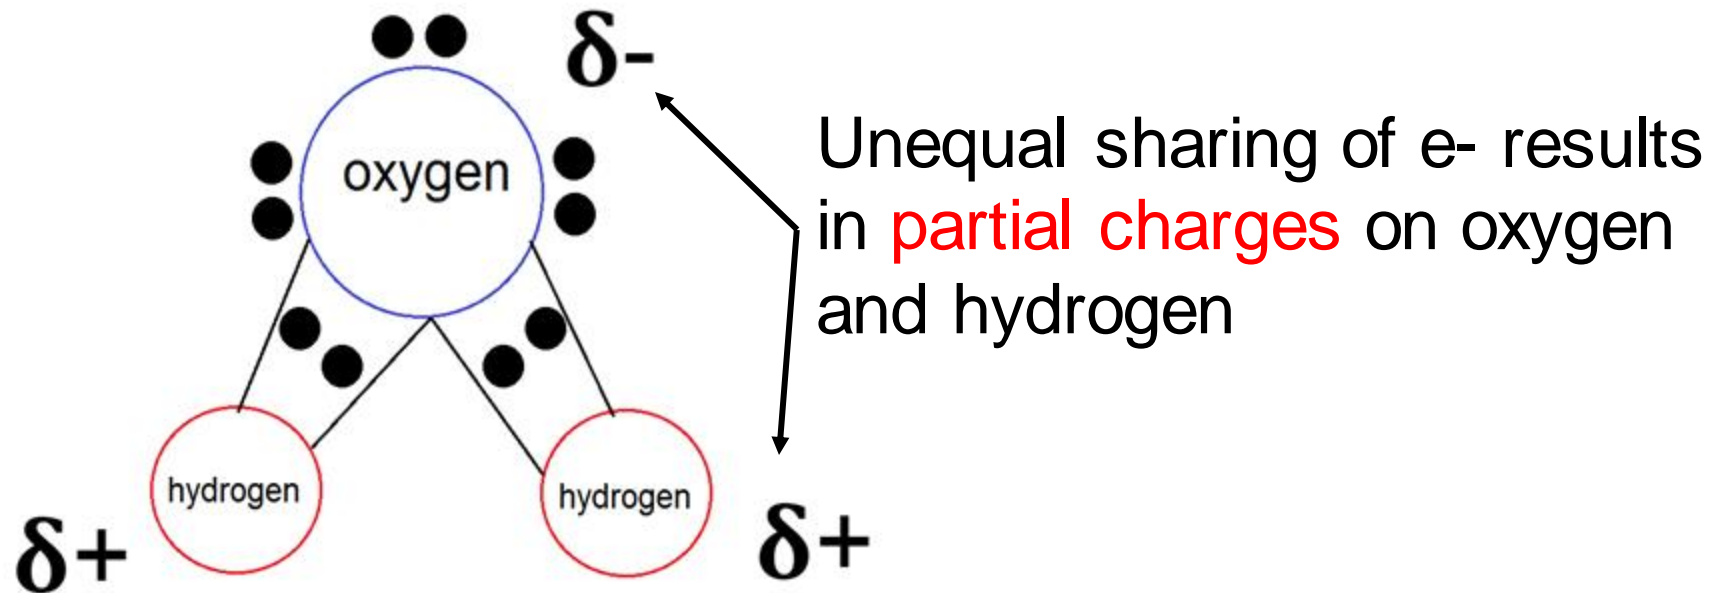

- Electrons are shared equally between two atoms

- Example:  $O_2$

# Types of Bonds

- Polar covalent
  - Electrons are not shared equally between two atoms
    - Example: H<sub>2</sub>O

# Types of Bonds

- **Ionic bonds**: The attraction between oppositely charged atoms (**ions**)
  - Usually between a metal and nonmetal (metal transfers electrons to nonmetal)
  - Forms ionic compounds and salts
    - NaCl
    - LiF
  - Occurs when there is a **transfer** of electrons from one atom to another atom forming ions
    - Cation: positively charged ion
    - Anion: negatively charged ion

# Types of Bonds

- Hydrogen bonds: the partially positive hydrogen atom in one polar covalent molecule will be **attracted** to an electronegative atom in another polar covalent molecule
  - Intermolecular bond: bond that forms **between** molecules

# Types of Bonds

- **Why does this happen?**
  - When a hydrogen atom is bonded to an electronegative atom (usually O, N, or F) the electrons are not being shared equally between atoms (remember: this is a **polar covalent bond**)
    - This causes the **hydrogen** to have a **partial positive charge** and the electronegative atom to have a **partial negative charge**

# Hydrogen Bonding

**Example:** hydrogen bonds between water molecules

# **Properties of water**

# Properties of Water

*Overview of the properties of water:*

- 1. Polarity*
- 2. Cohesion*
- 3. Adhesion*
- 4. Capillary action*
- 5. Temperature control*
  - a. High specific heat*
  - b. Evaporative cooling*
- 6. Floating ice*
- 7. Solvent*

# Properties of Water

1. **Polarity**: unequal sharing of the electrons make water a **polar molecule**

# Properties of Water

## 2. Cohesion:

attraction of molecules for other molecules of the same kind

- Hydrogen bonds between  $\text{H}_2\text{O}$  molecules hold them together and increase cohesive forces

Property allowing liquid to resist external force

- Allows for the transport of  $\text{H}_2\text{O}$  and nutrients against gravity in plants
- Responsible for surface tension

Cohesion:  
 $\text{H}_2\text{O}$   
molecules  
stick together

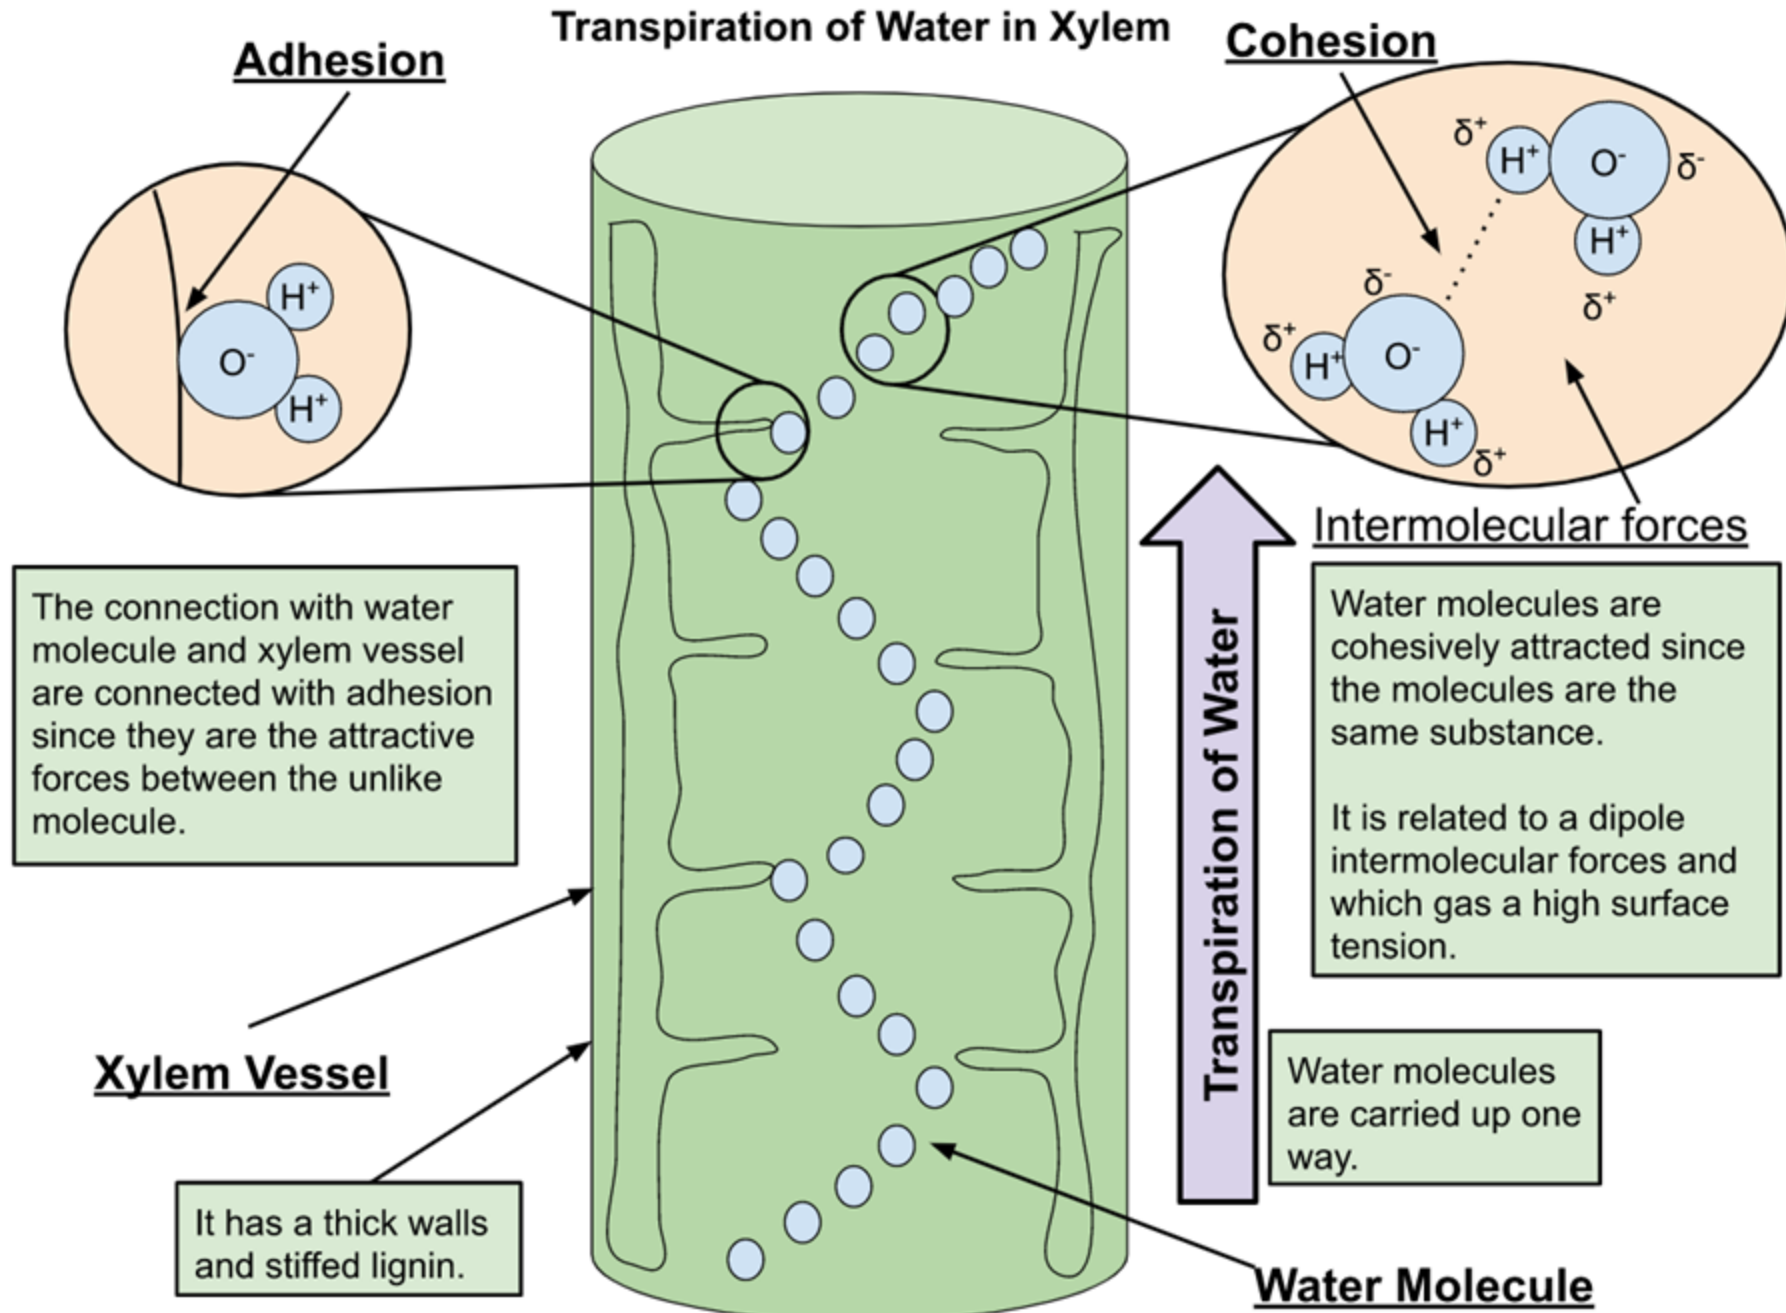

# Properties of Water

3. Adhesion: the clinging of one molecule to a different molecule

- Due to the polarity of  $\text{H}_2\text{O}$ 
  - In plants, this allows water to cling to the cell walls to resist the downward pull of gravity

Adhesion:  $\text{H}_2\text{O}$  molecules stick to the xylem wall

# Properties of Water

4. **Capillary Action**:  
the **upward**  
movement of water  
due to the forces of  
cohesion, adhesion,  
and surface tension

- Occurs when adhesion is greater than cohesion
  - Important for transport of water and nutrients in plants

Capillary action  
occurs moving  
water upwards

# Properties of Water

## 5. Temperature Control

### High Specific Heat: $\text{H}_2\text{O}$

resists changes in temperature

- How?
- Hydrogen bonds!
  - Heat must be absorbed to break hydrogen bonds, but heat is released when hydrogen bonds form

# Properties of Water

Importance of high specific heat:

- Moderates air temperature
  - Large bodies of water can absorb heat in the daytime and release heat at night
- Stabilizes ocean temp
  - Benefits marine life

Temp control properties of H<sub>2</sub>O stem from these hydrogen bonds

- Organisms can resist changes in their own internal temp

# Properties of Water

- Evaporative Cooling: water has a high **heat of vaporization**
  - The molecules with the highest **kinetic energy** leave as gas

# Properties of Water

Importance of  
evaporative cooling:

- Moderates Earth's climate
- Stabilizes temp in lakes and ponds
- Prevents terrestrial organisms from overheating (think sweating in humans)
- Prevents leaves from becoming too warm in the sun

# Properties of Water

6. Density (floating ice): as water solidifies it expands and becomes less dense
- Due to the hydrogen bonds
  - When cooled,  $\text{H}_2\text{O}$  molecules move too slowly to break the bonds
    - Allows marine life to survive under floating ice sheets

# Properties of Water

Hydrogen bonds cause water molecules to form a crystalline structure

Quick! Think, Pair, Share

Imagine the 3D crystalline structure of ice. How many hydrogen bonds can one molecule of water make with its neighboring water molecules?

**Answer:** four

# Properties of Water

7. Solvent: dissolving agent in a solution
- Water is a **versatile solvent**
    - Its polar molecules are attracted to ions and other polar molecules it can form hydrogen bonds with

**Solution**: homogenous mix of 2+ substances

**Solvent**: dissolving agent in a solution

**Solute**: substance that is dissolved

# Properties of Water

- “Like dissolves like”
- Water can interact with sugars or proteins containing many oxygen and hydrogen
- Water will form **hydrogen bonds** with the sugar or protein to dissolve it

# Properties of Water

## Ionic compounds

- The partially negative oxygen in water will interact with a positive atom
- The partially positive hydrogen in water will interact with a negative atom
- Dissolves ionic compounds

$\text{Na}^+$  surrounded by oxygen  
 $\text{Cl}^-$  surrounded by hydrogen
